[^0]Why Expansion Tanks are Important

Thermal expansion occurs when water is heated during non-use periods. The installation of a Pressure Reducing Valve (PRV), Check Valve or Back Flow Preventer "closes" the water system, leaving water with no room for expansion. National Standard Plumbing Code 10.5.7 requires backflow prevention, to prevent backflow into the water main.

Thermal expansion in a closed plumbing system can be damaging, dangerous and costly. Its effects include damage to water heater tank and connections, gas water heater flue tubes, pumps serving washers and dishwashers, leaking faucets, "weeping" of water through the water heater T\&P Safety Valve, and noisy water hammer in the pipes. Most water heater warranties do not cover failure due to thermal expansion.

A properly sized Expansion Tank eliminates these problems, by giving water a place to go when thermal expansion occurs. When a water heating cycle ends, or when any fixture is opened within the system, the impact of thermal expansion is reduced, and water drains out of the expansion tank

Expansion tanks are
Expansion tanks are pre-charged with
38 PSI. If the inlet water pressure is higher than 38 PSI, the expansion tank's air pressure must be adjusted to match that pressure but must not be higher than 80 PSI.

Why Well Tanks are Important
A well tank is an essential part of any well system,
delivering these benefits: - It ensures that your pump will run for at least one
minute each time it cycles, as required by pump manufacturers.

- It stores a supplemental water supply between pump cycles, to reduce the number of cycles throughout
the day, and helps prolong pump life.
- It helps maintain water pressure within your system, ensuring proper operation of your dishwasher and ashing machine, and robust flow for showering and bathing.

A properly sized pump and well tank will work as a team to meet your needs and will deliver many years of dependable service.

How to Size a Well Tank

1. If you know your current pump size, use columns 2 and 3 in the sizing chart below to make your tank selection.
2. If you do not know your pump size or the size of your current tank, count all your water fixtures. Be sure to include sinks, tubs, showerheads, outside faucets, utility sinks, dishwasher, washing machine, etc. Count
each fixture individually. Use columns 1 and 3 in the sizing chart below to make your tank selection.
3. If replacing a glass-lined or other "standard" tank with a diaphragm tank, use columns 3 and 4 in the sizing chart below to make your tank selection.

## 

How a Diaphragm Well Tank Works

1. START-UP CYCLE

Diaphragm is pressed against the bottom of the chamber.
2. FILL CYCLE

Water is pumped into the reservoir, which forces the diaphragm upward into the air chamber.
HOLD CYCLE
Pump-cutoff pressure is attained. Diaphragm reaches capacity.
4. DELIVERY CYCLE

Pump remains shut off while air pressure in top water to the systep diaphragm downward, delivering
